DenseCap: Fully Convolutional Localization Networks for Dense Captioning

Justin Johnson* Andrej Karpathy* Li Fei-Fei
Department of Computer Science, Stanford University
{jcojohns, karpathy, feifeili}@cs.stanford.edu

Abstract

We introduce the dense captioning task, which requires a computer vision system to both localize and describe salient regions in images in natural language. The dense captioning task generalizes object detection when the descriptions consist of a single word, and Image Captioning when one predicted region covers the full image. To address the localization and description task jointly we propose a Fully Convolutional Localization Network (FCLN) architecture that processes an image with a single round of optimization. The architecture is composed of a Convolutional Network, a novel dense localization layer, and Recurrent Neural Network language model that generates the label sequences. We evaluate our network on the Visual Genome dataset, which comprises 94,000 images and 4,100,000 region-grounded captions. We observe both speed and accuracy improvements over baselines based on current state of the art approaches in both generation and retrieval settings.

1. Introduction

Our ability to effortlessly point out and describe all aspects of an image relies on a strong semantic understanding of a visual scene and all of its elements. However, despite numerous potential applications, this ability remains a challenge for our state of the art visual recognition systems. In the last few years there has been significant progress in image classification [39, 26, 53, 45], where the task is to assign one label to an image. Further work has pushed these advances along two orthogonal directions: First, rapid progress in object detection [40, 14, 46] has identified models that efficiently identify and label multiple salient regions of an image. Second, recent advances in image captioning [3, 32, 21, 49, 51, 8, 4] have expanded the complexity of the label space from a fixed set of categories to sequence of words able to express significantly richer concepts.

However, despite encouraging progress along the label density and label complexity axes, these two directions have

* Both authors contributed equally to this work.

Figure 1. We address the Dense Captioning task (bottom right) with a model that jointly generates both dense and rich annotations in a single forward pass.

remained separate. In this work we take a step towards unifying these two inter-connected tasks into one joint framework. First, we introduce the dense captioning task (see Figure 1), which requires a model to predict a set of descriptions across regions of an image. Object detection is hence recovered as a special case when the target labels consist of one word, and image captioning is recovered when all images consist of one region that spans the full image.

Additionally, we develop a Fully Convolutional Localization Network (FCLN) for the dense captioning task. Our model is inspired by recent work in image captioning [49, 21, 32, 8, 4] in that it is composed of a Convolutional Neural Network and a Recurrent Neural Network language model. However, drawing on work in object detection [38], our second core contribution is to introduce a new dense localization layer. This layer is fully differentiable and can be inserted into any neural network that processes images to enable region-level training and predictions. Internally, the localization layer predicts a set of regions of interest in the image and then uses bilinear interpolation [19, 16] to smoothly crop the activations in each region.

We evaluate the model on the large-scale Visual Genome dataset, which contains 94,000 images and 4,100,000 region captions. Our results show both performance and speed improvements over approaches based on previous state of the art. We make our code and data publicly available to support further progress on the dense captioning task.

DenseCap: Fully Convolutional Localization Networks for Dense Captioning

Justin Johnson* Andrej Karpathy* Li Fei-Fei
Department of Computer Science, Stanford University
{jcojohns, karpathy, feifeili}@cs.stanford.edu

Abstract

abstract

We introduce the dense captioning task, which requires a computer vision system to both localize and describe salient regions in an image in natural language. The dense captioning task is a generalization of image captioning when the descriptions are localized to specific regions of the image. To address the localization problem, we propose a Fully Convolutional Localization Network (FCLN) architecture that processes an image with a single, efficient forward pass, requires no external region proposals, and can be trained end-to-end with a single round of optimization. The architecture is composed of a Convolutional Network, a novel dense localization layer, and Recurrent Neural Network language model that generates the label sequences. We evaluate our network on the Visual Genome dataset, which comprises 94,000 images and 4,100,000 region-grounded captions. We observe both speed and accuracy improvements over baselines based on current state of the art approaches in both generation and retrieval settings.

1. Introduction

task

essentially point out and describe all aspects of an image with a strong semantic understanding of all of its elements. However, despite duplications, this ability remains a challenge for the art visual recognition systems.

SotA

In the last few years there has been significant progress in image classification [39, 26, 53, 45], where the task is to predict a single label for the whole image. Further work has pushed the state of the art in two orthogonal directions: First, rapid object detection [40, 14, 46] has identified modern methods to identify and label multiple salient regions in an image. Second, recent advances in image captioning [3, 32, 21, 49, 51, 8, 4] have expanded the complexity of the label space from a fixed set of categories to sequences of words. Together, these two directions have significantly enriched the label space.

flaw

Encouraging progress along the localization and captioning axes, these two directions have remained separate. In this work we take a step towards unifying these two inter-connected tasks into one joint task. First, we introduce the dense captioning task (Figure 1), which requires a model to predict a set of labels across regions of an image. Object detection can be recovered as a special case when the target labels consist of one word, and image captioning is recovered when all images consist of one region that spans the full image.

figure 1

Figure 1. We address the Dense Captioning task (bottom right) with a model that jointly generates both dense and rich annotations in a single forward pass.

idea

remained separate. In this work we take a step towards unifying these two inter-connected tasks into one joint task. First, we introduce the dense captioning task (Figure 1), which requires a model to predict a set of labels across regions of an image. Object detection can be recovered as a special case when the target labels consist of one word, and image captioning is recovered when all images consist of one region that spans the full image.

Additionally, we develop a Fully Convolutional Localization Network (FCLN) for the dense captioning task. Our model is inspired by recent work in image captioning [49, 21, 32, 8, 4] in that it is composed of a Convolutional Neural Network and a Recurrent Neural Network language model. However, drawing on work in object detection [38], our second core contribution is to introduce a new dense localization layer. This layer is fully differentiable and can be inserted into any neural network that processes images to enable region-level training and predictions. Internally, the localization layer predicts a set of regions of interest in the image and then uses bilinear interpolation [19, 16] to smoothly crop the activations in each region.

We evaluate the model on the large-scale Visual Genome dataset, which contains 94,000 images and 4,100,000 region-grounded captions. Our results show both performance and speed improvements over approaches based on previous work. We make our code and data publicly available to support further progress on the dense captioning task.

remained separate. In this work we take a step towards unifying these two inter-connected tasks into one joint framework. First, we introduce the dense captioning task (see Figure 1), which requires a model to predict a set of descriptions across regions of an image. Object detection is hence recovered as a special case when the target labels consist of one word, and image captioning is recovered when all images consist of one region that spans the full image.

Additionally, we develop a Fully Convolutional Localization Network (FCLN) for the dense captioning task. Our model is inspired by recent work in image captioning [49, 21, 32, 8, 4] in that it is composed of a Convolutional Neural Network and a Recurrent Neural Network language model. However, drawing on work in object detection [38], our second core contribution is to introduce a new dense localization layer. This layer is fully differentiable and can be inserted into any neural network that processes images to enable region-level training and predictions. Internally, the localization layer predicts a set of regions of interest in the image and then uses bilinear interpolation [19, 16] to smoothly crop the activations in each region.

We evaluate the model on the large-scale Visual Genome dataset, which contains 94,000 images and 4,100,000 region-grounded captions. Our results show both performance and speed improvements over approaches based on previous work. We make our code and data publicly available to support further progress on the dense captioning task.

Abstract

We introduce the dense captioning task, which requires a computer vision system to both localize and describe salient regions in images in natural language. The dense captioning task generalizes object detection when the descriptions consist of a single word, and Image Captioning when one predicted region covers the full image. To address the localization and description task jointly we propose a Fully Convolutional Localization Network (FCLN) architecture that processes an image with a single, efficient forward pass, requires no external regions proposals, and can be trained end-to-end with a single round of optimization. The architecture is composed of a Convolutional Network, a novel dense localization layer, and Recurrent Neural Network language model that generates the label sequences. We evaluate our network on the Visual Genome dataset, which comprises 94,000 images and 4,100,000 region-grounded captions. We observe both speed and accuracy improvements over baselines based on current state of the art approaches in both generation and retrieval settings.

1. Introduction

Our ability to effortlessly point out and describe all aspects of an image relies on a strong semantic understanding of a visual scene and all of its elements. However, despite numerous potential applications, this ability remains a challenge for our state of the art visual recognition systems. In the last few years there has been significant progress in image classification [39, 26, 53, 45], where the task is to assign one label to an image. Further work has pushed these advances along two orthogonal directions: First, rapid progress in object detection [40, 14, 46] has identified models that efficiently identify and label multiple salient regions of an image. Second, recent advances in image captioning [3, 32, 21, 49, 51, 8, 4] have expanded the complexity of the label space from a fixed set of categories to sequence of words able to express significantly richer concepts.

However, despite encouraging progress along the label density and label complexity axes, these two directions have

* Both authors contributed equally to this work.

Figure 1. We address the Dense Captioning task (bottom right) with a model that jointly generates both dense and rich annotations in a single forward pass.

remained separate. In this work we take a step towards unifying these two inter-connected tasks into one joint framework. First, we introduce the dense captioning task (see Figure 1), which requires a model to predict a set of descriptions across regions of an image. Object detection is hence recovered as a special case when the target labels consist of one word, and image captioning is recovered when all images consist of one region that spans the full image.

Additionally, we develop a Fully Convolutional Localization Network (FCLN) for the dense captioning task. Our model is inspired by recent work in image captioning [49, 21, 32, 8, 4] in that it is composed of a Convolutional Neural Network and a Recurrent Neural Network language model. However, drawing on work in object detection [38], our second core contribution is to introduce a new dense localization layer. This layer is fully differentiable and can be inserted into any neural network that processes images to enable region-level training and predictions. Internally, the localization layer predicts a set of regions of interest in the image and then uses bilinear interpolation [19, 16] to smoothly crop the activations in each region.

We evaluate the model on the large-scale Visual Genome dataset, which contains 94,000 images and 4,100,000 region captions. Our results show both performance and speed improvements over approaches based on previous state of the art. We make our code and data publicly available to support further progress on the dense captioning task.

STEP 2: WRITE!

STEP 2: WRITE!

By now, you should have your introduction outlined in several dozen bullets, so the rest should be much easier

This would be a good time to run it by others

Expand each bullet into sentence/paragraph

Fill in details along the way

STEP 3: EDIT EDIT EDIT

STEP 3: EDIT EDIT EDIT

Some lucky people can write near-perfect text in one go

Most of us are not so lucky

I re-write my drafts many times, sometimes dozens

Important to get feedback from your advisor/labmates

THAT'S IT!

Now you just have the rest of the paper to write :)
